

## Answers to Question 2

### Simply Supported Beam

$$M_{\max} = w_{(\text{udl})}L^2/8 = 10 \times 10^2/8 = 125 \text{ kNm}$$

$$\begin{aligned} \Delta n &= 5w_{(\text{udl})}L^4/384EI \\ &= 5 \times 10 \times 10000^4 / 384 / 205 \times 10^3 / 615 \times 10^6 \\ &= 10.3 \text{ mm} \end{aligned}$$

## Answers

2(a)

**10m span ( $7/\cos 45^\circ$ ); peak load 15kN/m**- See above. Multiply Area load x loaded width.

2(b)

**125kNm** - This is  $wl^2/8$  for a uniformly distributed line load (UDL) of 10kN/m; obtained from the peak triangular load.  $(15 \times 2/3)$  with reference to figure 2.2.8. Slightly *under* is to assume UDL 50% peak, but this is not 'conservative' (slightly under at **94kNm**). Actual triangular loading moment is **97kNm**.

2(c)

**10.3mm** - Deflection from figure 2.2.3 [ $5wl^4/(384EI)$ ]. UDL from 2(b) above of 10kN/m. Actual triangular load deflection is **7.8mm (7.7mm for UDL 50% peak)**.

2(d)

**50kN for both cases**. Maximum shear for the triangular loading is under the support on the right hand side (RHS). Using the equivalent UDL will always give a safe shear/support reaction.
